Introduction

Linkage disequilibrium (LD) and linkage analyses have been extensively used to identify quantitative trait loci (QTL) in human and livestock species. Recently, interest in whole genome fine mapping and especially genome-wide selection has grown as a result of the dramatic increase in the number of known single nucleotide polymorphisms (SNP) and the decrease in genotyping costs. The access to dense marker maps has opened up the possibility for new approaches for fine mapping and genome wide selection. However, even though genotyping costs have substantially decreased, large scale genome-wide association studies are still costly. For this reason most of studies suffer from small sample sizes or from low marker density. Simulation is a highly valuable tool for assessing and validating proposed methods for QTL mapping and genome wide selection at very low cost, allowing also for the prediction of future changes in genetic parameters. During the last few decades, simulation has played a major role in population genetics and genomics.

Simulating and analyzing livestock genomic data differ in several aspects from analyses carried out in humans. For instance, in livestock a common strategy for detecting QTL is either to use multigenerational pedigrees, large family sizes, in which artificial insemination is practiced, or to design a crossbreeding program, such as F2 and back crosses (Andersson, 2001). More importantly, human populations have been experiencing an expansion in effective population size (Ne), while Ne in livestock populations has decreased. Consequently LD in livestock extends over longer distances than in humans. Moreover, combined LD and linkage QTL mapping has attracted more attention in livestock due to strong family structure (Meuwissen et al., 2002). Therefore, the population structure is crucial to identify and correctly interpret the associations between molecular and phenotypic diversity (Pritchard and Rosenberg 1999; Buckler and Thornsberry 2002).

QMSim was designed to simulate a wide range of genetic architectures and population structures in livestock. Large scale genotyping data and complex pedigrees can be efficiently simulated. Simulation is basically carried out in two steps. In the first step, historical generations are simulated to create desirable level of LD and, in the second step, recent population structures are generated, which can be very complex. QMSim allows for a wide range of parameters to be incorporated in the simulation models in order to produce appropriate simulation data.

In order to create initial LD and to establish mutation-drift equilibrium, a historical population can be simulated by considering only two evolutionary forces: mutation and drift. Mutation constantly introduces new variation and genetic drift shifts the variation to fixation. Here, the mating system is based on the union of gametes randomly sampled from the male and female gametic pools. After generating historical generations, the recent populations are simulated. Expansion and contraction of both historical and recent populations are allowed. In the recent generations selection and culling can be implemented based on different criteria such as phenotypes, true genetic values and estimated breeding values for single trait with predefined heritability and phenotypic variance. Estimated breeding values may be generated using four different approaches: 1) Best linear unbiased prediction (BLUP) via an animal model, 2) based on predefined accuracy, 3) approximated based on the number of offspring with record and 4) breeding values for each generation can be externally estimated by any method and then be inputted to QMSim. Mating design can be random, assortative (positive or negative) or optimized to minimize or maximize inbreeding. The mating design that maximizes inbreeding allows one to quickly create an inbred line. Optimization of inbreeding is carried out using simulated Annealing method (Sonesson and Meuwissen, 2000). The program can simulate sex limited traits, such as milk production. Owing to the object-oriented programming, it is easy to simulate multiple populations with different structures and selection criteria. QMSim has flexibility in simulating wide range of population structures. For example, in livestock, some of QTL mapping designs involve line crosses produced from inbred lines with divergent phenotypes. In this case, the associated mutations are expected to have high frequencies in opposite directions. Another example is simulation of two lines coming from the same base population to assess accuracy of genomic breeding values for a particular genomic evaluation method. Here, one line can be treated as training set and the other one as validation set. These scenarios can readily be simulated by QMSim.

A wide range of parameters can be specified for simulating the genome, such as: mutation rate, crossover interference, number of chromosomes, markers and QTL, location of markers and QTL, number of alleles, allelic frequencies, allelic effects, missing marker rate, and genotyping error rate. This flexibility permits for a wide variety of genetic architectures to be considered. No allelic effects are simulated for markers, so they are treated as neutral. For QTL, additive allelic effects can be sampled from gamma, normal or uniform distributions. Alternatively, predefined relative additive variance for each QTL can be supplied by the user.

One important aspect of genome simulation is to model the recombination appropriately to produce realistic level of LD, given the recent and past population structures. QMSim models crossover process, using a Poisson model. This is done by sampling the number of crossovers from a Poisson distribution and then the crossovers are located randomly across the chromosome. Because the input map is in centiMorgan it is straightforward to take into account the pattern of recombination hotspots and coldspots along the genome by adjusting the distances between markers. Moreover a simple algorithm is applied to account for crossover interference. To establish mutation-drift equilibrium in the historical generations either infinite-allele mutation model or recurrent mutation model is used. The infinite-allele mutation model assumes that a mutation creates a new allele, while the recurrent mutation model assumes that a mutation alters an allelic state to another and does not create a new allele. In the recurrent model, transition probabilities from one allelic state to another are assumed equal. Different mutation rates for markers and QTL can be specified. Effect of mutant QTL alleles can be drawn from gamma, normal or uniform distribution. The number of mutations is sampled from a Poisson distribution and it is assumed that mutation rates are equal for all loci within markers and within QTL.

The most important parameters affecting CPU time and memory are the number of loci (markers and QTL) and population size. However, depending on the simulation scenario, other parameters such as high mutation rate, calculation of LD for dense marker panels, calculation of inbreeding, saving huge outputs, etc might become a computational bottleneck. QMSim provides the user with enough options to manage the outputs or turn off unwanted computations. For example, one may optionally save genotypes for last few generations avoiding large outputs.

There are two versions of QMSim, a 8-bit version and a 16-bit version. The 8-bit version allows for maximum 255 alleles per locus while 16-bit version allows for maximum 65,535 alleles per locus. The 16-bit version might be useful for specific scenarios such as one where unique alleles for each founder are to be simulated.

QMSim main features:

- ✓ Simulates historical generations to establish mutation-drift equilibrium and create linkage disequilibrium.
- ✓ Recombination is appropriately modeled. Interference is allowed.
- Multiple chromosomes, each with different or similar density of markers and QTL maps, can be generated.
- \checkmark Very dense marker map and also sequence data can be simulated.
- \checkmark Missing genotypes and genotyping errors can be simulated.
- ✓ Markers can be either SNP or microsatellites.
- \checkmark Males and females can have different genome length in cM.
- ✓ Unbalanced sex ratio is also allowed in historical populations.
- ✓ Additive QTL effects can be simulated with different distributions, such as gamma, normal or uniform.
- ✓ In addition to QTL effects, polygenic effect can be included.
- ✓ After mutation-drift equilibrium, polymorphic marker panel with pre-defined MAF threshold and QTL can be selected.
- ✓ 16-bit version allows for assigning unique alleles to each founder.
- ✓ Complete linkage disequilibrium in the first historical generation can be generated.
- ✓ Calculates LD decay in specified generations.
- ✓ Population expansion or bottleneck is allowed for both historical and recent populations.
- ✓ Selection and culling of breeding population can be carried out based on different criteria, such as phenotypes, estimated breeding values (can be calculated and inputted by the user) and true breeding values.

- \checkmark More than one litter size with predefined probabilities can be considered.
- ✓ Multiple recent populations or lines can be simulated. Crossing between populations or lines is allowed.
- ✓ Multiple populations can be analyzed jointly for estimating breeding values and computing inbreeding.
- ✓ Creates detailed output files. Outputs can be customized to avoid saving unnecessary data.
- ✓ Equipped with fast and high-quality pseudo-random number generators.
- ✓ Computationally efficient.

Computing environment:

The code is written in C++ language using object oriented techniques and the application runs on Windows and Linux platforms.

Download:

The executable files are available for Windows and Linux at http://www.aps.uoguelph.ca/~msargol/qmsim/

Input parameter file

The program requires a parameter file, in which various parameters for the simulation should be specified. The input parameter file must be in ASCII format. The C++ like comments can be used to add descriptive anywhere in the parameter file. The parameter file consists of five main sections. The first part describes global parameters, the second part describes the historical population, the third part describes parameters for subpopulations and generations, the fourth part contains genome parameters and the fifth part is related to the output options. The order of commands within each section is not normally important. All commands end with a semicolon. Failure to include the semicolon will cause an error message and program exits.

1- GLOBAL PARAMETERS SECTION:

title	

Description: Usage:	<pre>title = "string";</pre>	· · · · · · · · · · · · · · · · · · ·
Type: Default:	string Optional None	indicates an arbitrary title.

seed

Description:	Set a user-specified seed.	
Usage:	seed = "filename";	
	filename	indicates a seed file name.
Type:	Optional	
Default:	"seed"	
Note:		

Initialization of the random number generator requires a seed. If seed file is not specified, the random number generator will be seeded from the system clock. For each run the initial seed numbers will be backed up in output folder. This allows one to generate the same simulated data. Therefore, one can backup only the seed file instead of backing up whole data and, if needed, generate the same data set in the future or on a remote system with the same version of the software as the one the seed number was generated. At beginning of each run initial seed numbers are written in "seed.prv". For next run, the seed derived from the system clock will be compared with "seed.prv" to ensure that the same seed is not used. "seed.prv" file can be accessed by only one process at a time, therefore if two jobs are started at the same time and in the same folder they will be seeded with different seed. The Mersenne Twister algorithm, which is a high-quality fast random number generator, is used to generate random numbers (Matsumoto and Nishimura, 1998).

nthread			
Description:	Number of threads for parallel processing.		
Usage:	nthread = value;		
-	value is the number of threads.		
	Range: 1 – 200		
Type:	Optional		
Default:	Auto		
Note:	Number of CPUs is automatically detected. If you are running on a busy server then you may want to restrict the number of threads to available CPUs.		
	Please note that you may not observe a linear relation between speed and the number of threads since the main bottleneck is memory access.Some functions run only on single processor like GBLUP function of Inbreeding Optimization function.		
	It is important to note that when QMSim runs with the same seed number but on two machines with different number of CPU cores, different data sets may be generated. To be able to re-generate the same data set using a stored seed on two machines, the two machines should have same number of CPU cores or "nthread" should be set to 1 for both runs.		

nrep

Description: Usage:	Number of replicates. nrep = value;	
-	value is the number of replicates.	
	Range: $1 - 20,000$	
Type:	Mandatory	
Note:	While the simulation is in process, user can adjust (decrease or increase) the number of replicates by creating file "nrep.txt" in output folder. The content of the file should be one integer number only, which indicates the adjusted number of replicates.	

h2

Description:	Overall heritability (Polygenic plus QTL)	
Usage:	h2 = value;	
	value	is heritability.
		Range: $0-1$
Type:	Mandatory	

qtlh2 Description: QTL heritability

Usage:	qtlh2 = value; value	is heritability attributable to QTL. Range: $0-1$
Type:	Mandatory	
Note:	 Mandatory In the last historical generation, the QTL allelic effects are scaled to ensure the desired QTL variance. If qtlh2 is set to a value smaller than h2 then a polygenic (infinitesimal) effect is also simulated. When qtlh2 is zero, no QTL effect is simulated and therefore pure polygenic effect is simulated. 	

phvar

Description:	Phenotypic variance		
Usage:	phvar = value;		
	value	is pheno	otypic variance.
		Range:	0-10,000,000
Type:	Mandatory		

no_male_rec

Description:No record for males will be simulated.Usage:no_male_rec;Type:OptionalNote:This option is used to simulate a sex limited trait like milk yield. When
males do not have records, but the selection or culling design is based on
phenotypes, males will be randomly selected or culled.

skip_inbreeding

Description: Inbreeding will not be calculated.

Usage: skip_inbreeding;

Type: Optional

Note: Inbreeding is calculated in recent populations only. Calculation of inbreeding is a time consuming task in large populations. To gain speed in simulating large populations, one can safely turn off calculation of inbreeding when: 1) no polygenic effect is simulated (i.e., all the genetic variance is explained by QTL), 2) BLUP-breeding values are not estimated and 3) matings are not optimized to minimize or maximize inbreeding. Inbreeding can be skipped for the above mentioned situations but results should be interpreted with caution.

joint_pop

Description: When more than one population is defined, populations will be analyzed jointly. Usage: joint_pop;

Type:	Optional
Default:	If not specified populations will be analyzed separately.

system			
Description: Usage:	Runs a system executable file at the end of each replicate. system = "command" /option;		l of each replicate.
	command	is a system command.	
	option	/nrep	passes the current replicate number as the last argument to the external program.
Type:	Optional		
Note:	System command is useful when simulating larger number of replicates each with large genotype data. After each replicate the genotype data can be analyzed with an external program and then be removed.		

2- HISTORICAL POPULATION SECTION:

In order to create initial LD and to establish mutation-drift equilibrium, a historical population can be simulated by considering equal number of individuals from both sexes, discrete generations, random mating, no selection and no migration. Offspring are produced by random union of gametes, each from the male and female gametic pools. Expansion and contraction of the historical population size are allowed. Historical population is simulated based on forward-time approach. The current version of QMSim can only simulate a single historical population.

begin_hp & end_hp

Description:	Beginning and end of the historical population parameters
Usage:	begin_hp;
	end_hp;
Type:	Mandatory

hg_size

Description:	Historical generat	tion sizes
-	0	
Usage:	$hg_size = v1 [v2]$	
	v1	indicates the historical generation size
		Range: 2 – 100,000
	v2	indicates the historical generation number
		Range: $0 - 150,000$
Type:	Mandatory	
Example1:	hg_size = 500 [0]] 500 [1000];
	One thousand his	storical generations with constant size of 500

Example2: Note:	hg_size = 2000 [0] 400 [1000]; One thousand historical generations with gradual decrease in size from 2000 to 400. The decrease is linear. By using appropriate historical generation sizes different form of historical bottleneck or expansion can be simulated. Generation number starts always from zero therefore the first historical generation number must be always zero.
nmfhg Description: Usage:	The number of males in the first historical generation nmfhg = value; value indicates the number of males in the first historical generation. Range: 1 – 100,000
Type: Default: Note:	Optional equal number of individuals from each sex The sex ratio will be constant across historical generations. However, if one wishes the sex ratio can be changed in the last historical generation only.
nmlhg Description: Usage:	The number of males in the last historical generation nmlhg = value; value indicates the number of males in the last historical generation. Range: 1 – 100,000
Type: Default:	Optional same sex ratio as the first historical generation

3- POPULATION SECTION:

This section can contain more than one recent population and parameters for each population should surrounded by begin_pop and end_pop. Founders for each population can be chosen from the historical population or from the other recent populations. Multiple recent populations can be analyzed separately (by creating one distinct pedigree for each population) or jointly (by creating one pedigree for all populations) for inbreeding and estimated breeding values. To perform joint analysis use joint_pop command. Up to 1,000 recent populations can be simulated.

begin_pop & end_pop

Description:	Beginning and end of the population parameters
Usage:	<pre>begin_pop = "string";</pre>
	end_pop;

string

indicates an arbitrary name of population (maximum 20 characters).

Type: Mandatory

Choosing founders for a population:

begin_founder; and end_founder; should be used at the beginning and end of this subsection.

For the first defined recent population founders must come from the last historical generation. However, for subsequent populations (if defined) founders can be also chosen from one or more (up to 10) previously defined populations. Founders can be chosen from specified generations of previous populations based on different criteria. One can simulate migration by choosing founder groups from different populations (see example 12).

Note that for separate analysis of multiple populations (when EBV is to be estimated) EBVs for founders of each population are estimated separately and based on no pedigree information, disregarding which population they are selected from.

If founders from two or more populations are to be selected (not randomly) from a particular generation of the population, then the order in which populations are defined becomes important. Note that populations are processed in the order they are defined.

begin_founder & end_founder

—
Beginning and end of parameters for choosing founders
begin_founder;
end_founder;
Mandatory

male

Description: Usage1: Usage2:	Selecting base males from particular population and generation male $[n = v1, pop = "s1", gen = v2, select = v3 option1]$ option2; male $[n = v1, pop = "hp", select = v3 option1]$ option2;			
	v1	is the number of male individuals to be selected.		
		Range: 1–50,000		
	s1	is the name of population.		
	hp	historical population (last historical generation).		
	v2	is the generation number.		
		Range: $0 - 2,000$ indicates the type of selection (optional).		
	v3			
		Range: rnd, phen, tbv and ebv		
		Default: rnd		
	option1	/l to select low values		
		/h to select high values		
		Default /h		

	option2	/not_founder_yet	to select individuals that have not appeared as founders of any recent populations	
Type:	Mandatory			
Note:	options /l and /h cannot be used when selection method is random.			
	1		from the last historical generation.	
	•	2	last historical generation, selection	
		be based on 'ebv'.	,	
			once in order to choose male founders	
	from afferent g	enerations or population	18.	

female

Description:	Selecting base females from particular population and generation
Usage:	the same as for males

ng

Description:	the number of generations for current population		
Usage:	ng = value;		
	value	is the number of generations for current population.	
		Range: $0 - 2,000$	
Type:	Mandatory		

ls

Description:	Litter size		
Usage1:	ls = value;		
Usage2:	ls = v1 v2 [p2] v3	3 [p3];	
	value v1 v2 v3	are the litter sizes or the numbers of progeny per dam.	
		Range: $0 - 1,000$	
	p2 p3	are the probabilities of the litter sizes.	
		Range: $0-1$	
Tune	Mandatory		
Type:	5	and developed to make the second	
Note:	The litter size is considered to not be controlled genetically. The litter sizes are uniformly sampled based on the provided litter size probabilities.		
	In usage2, the probability of the first litter size is not required because the		
	sum of probabilit	ies is 1.	
pmp			
Description:	The proportion of	f male progeny	

Usage:	pmp = value	e option;
	value	is the proportion of male progeny.
		Range: $0-1$

	option	/fix	sex is assigned at random, but it is ensured that observed proportion of males will be equal to the specified value.
		/fix_litter	this causes sex ratio be fixed within litters (progeny of a dam). For example, the command "pmp = 0.5 /fix_litter;", when litter size is 2 will always generate one male and one female progeny per dam.
Type: Default:	Optional 0.5		

md

Description:	Mating design			
Usage:	md = value optio	d = value option;		
	value	is the type of mating	design	
		Range: rnd, rnd_ug	, minf, maxf, p_assort, n_assort	
	option	/phen	assortative mating base on	
			phenotype	
		/ebv	assortative mating base on ebv	
		/tbv	assortative mating base on the	
Type:	Optional		C	
Default:	rnd			
Note:		used only for assortat	ive mating design (i.e., p_assort and	
11000	n_assort).	used only for ussorial	ave maning design (nei, p_assore and	
	_ /	or random union of ga	metes. With this design offspring are	
	U	0	one randomly sampled from the male	
			netic pool. Therefore a dam can mate	
			ation. Note that with rnd_ug mating	
		0	8 8	
	 design, 'ls' (litter size) is treated as average number of progeny per dam. p_assort and n_assort stand for positive assortative and negative assortative, respectively. In the assortative mating design, sires mate to dams based on similarity (positive) or dissimilarity (negative). Similarity and dissimilarity can be based on true breeding values (tbv), estimated breeding values (ebv) or phenotypes (phen). Designs minf and maxf minimizes and maximizes inbreeding, repectively. In the optimized mating design, pairs of mates are chosen so that inbreeding is 			
			generation. To minimize or maximize	
			od is used (Sonesson and Meuwissen,	
	,	0	od is an adaptation of the Metropolis-	
			optimization problem. The initial	
			creased by a factor of 0.9.	
	In culling of pare	ents and selection of pr	rogeny, minimization or maximization	

of inbreeding is not considered.

sr					
Description:	Sire replacement				
Usage:	sr = v1 v2 [v3] option;				
-	v1				
		Range: $0-1$			
	v2	is the sire population	growth rate		
		Range: $-1-5$			
	v3	is starting generation	number		
	option	/e	exponential growth rate		
Type:	Optional				
Default:	1 (i.e., discrete g	enerations)			
Example1:	sr = 0.5;				
		ould be replaced in al	l generations (sire population growth		
_	rate is zero)				
Example2:	$sr = 0.5 \ 0.2;$				
			be culled in each generation and sire		
	population size grows constantly across generations at rate 0.2. The number				
	of male progeny to be selected would be larger than the number of culled sires because of increase in the sire population size				
Enomento2.			bulation size		
Example3:	sr = 0.4 [1] 0.5 [3]		ad from concretion 1 to concretion 5		
	40% of sire population would be culled from generation 1 to generation 5 and 50% from generation 5 afterward (sire population growth rate is zero)				
Example4:	0		she population growth rate is zero)		
Example4.	sr = $0.5 - 0.1 [1] 0.5 0.0 [5];$ 50% of current sire population would be culled in each generation but sire				
			e first 5 generation and zero afterward		
Note:	1 1 0		to replace the culled sires, the culling		
11010.			on growth rate is negative and if the		
		11	rate, the culling rate will increase. In		
		a warning message wil			
			rent generation increases/decreases by		
			his option is not specified size of the		
	1	6	s by $v^2 *$ size of starting generation		
	(i.e., generation				
	-				

dr

Description:	Dam replacement		
Usage:	dr = v1 v2 [v3] option;		
	v1	is the proportion of dam population to be culled	
		Range: $0-1$	
	v2	is the dam population growth rate	
		Range: $-1-5$	

	v3	is starting generation number /e exponential growth rate	
	option		
Type:	Optional		
Default:	1 (i.e., discrete g	enerations)	
Example:	See sr for examp	les	

sd

Description: Usage:	Selection design sd = value option;			
U	value	is the type of selection design		
		Range: rnd, phen, t	bv and ebv	
	option	/1	to select low values	
		/h	to select high values	
		Default	/h	
Type:	Optional			
Default:	rnd			
Note:	options /l and /h cannot be used when selection design is random. option /l forces the program to select individuals with low phenotype, tbv or ebv values and option /h does the opposite.			

cd

Description: Usage:	Culling design cd = value option	e		
U	value	is the type of culling	g design	
		Range: rnd, phen,		
	option	/1	to select low values	
	•	/h	to select high values	
		Default	/h	
Type:	Optional			
Default:	age			
Note:	options /l and /h	cannot be used when	culling design is random or age.	
	option /l forces the program to select individuals with low phenotype, tbv or ebv values and option /h does the opposite. If culling design is age and selection design is not random then culling is first based on age and second based on the selection design with opposite			
	direction within	age group. For instand	ce, if culling is set to age and selection	
	is set to tbv /h, th	ne culling within each	age group is based on tbv /l.	

ebv_est

l	
ebv_est = approx option1;	

		/mnp_female v2		
	v1, v2	mber of progeny with record for male and		
		female individua	ls (default is zero)	
		Range: $0 - 1,00$)0	
Usage3:	ebv_est = accu	r v option;		
Usage4:	ebv_est = accu	r_male v1 accur_fen	nale v2 option;	
-	v, v1, v2	are predefined ac	curacies	
		Range: $0-1$		
	option	/true_av	true additive genetic variance for	
			each generation will be considered	
Usage5:	$ebv_est = exte$	rnal_bv "external so	lver filename";	
Type:	Optional			
Default:	None			
Note:	If ebv_est statement is specified, QMSim will estimate breeding value for each individual.			
	Breeding valu	e can be defined as a	a measure of the additive genetic value of	
	an individual as a parent.			
	Three methods	s are implemented to	estimate breeding values:	

1) blup

The best linear unbiased prediction (BLUP) of breeding values are obtained by Henderson's (Henderson, 1975) mixed linear model. The BLUP predictor has the smallest prediction error variance among all possible linear unbiased predictors. Two pieces of information are used: phenotypic records and pedigree data. The numerator relationship matrix (**A**) is used in the following mixed model equations to derive BLUP of random additive effects (including polygenes and QTL):

$$\left[\mathbf{Z}'\mathbf{Z}+\mathbf{A}^{-1}\frac{\sigma_{e}^{2}}{\sigma_{a}^{e}}\right]\left[\hat{\mathbf{a}}\right]=\left[\mathbf{Z}'\mathbf{y}\right],$$

where **y** is the vector of phenotypic records, **Z** is the incidence matrix relating the records to the random additive effects (**a**), σ_e^2 is the residual variance and σ_a^2 is the additive genetic variance.

The mixed model equations are solved by the conjugate gradient method. For multiple population case, all individuals are included in the mixed model equations.

2) approx

When there is enough number of half-sib offspring per individual, EBV can be approximated with a good accuracy. More importantly, when dealing with a sex limited trait like milk yield, records on relatives such as half-sib progeny can be used to generate estimated breeding values for the sires, using the following simple formula:

$$EBV = \frac{N \times (TBV + \frac{2 \times NRND \times \sigma_e^*}{\sqrt{N}})}{N + \frac{4 - h^2}{h^2}}$$

where N is the progeny size, TBV is true breeding value, σ_e^* is residual standard deviation for a sire model ($\sigma_e^* = \sqrt{\sigma_e^2 + \frac{3}{4}\sigma_a^2}$), h^2 is heritability

and NRND is normal random deviate.

It is assume that progeny are paternal half-sibs and additive genetic variance is constant across generations. For individuals with no progeny, parental average is calculated (for founders own record is used to estimate EBV at the start). If minimum number of progeny with record is specified and an individual has fewer progeny with record in the pedigree then some dummy progeny will be considered to reach the minimum number.

3) accur

In this case, breeding values are approximated based on a predefined accuracy. Some methods for estimating breeding values might be very time consuming such as Bayesian methods to estimate breeding values using dense genetic markers (Meuwissen et al., 2001). But, knowing the accuracy for a method, computing breeding values with predefined accuracy allows one to roughly evaluate the future changes in the genetic parameters based on the assumed method.

Note that accuracy would be constant across generations if true additive genetic variance for each generation is considered, otherwise the initial additive genetic variance will be used then the loss of genetic variation will affect the accuracy.

4) external_bv

With this option, user should estimate breeding values from temporary data outputted by QMSim in each generation. The estimated breeding values should then be provided to QMSim for selection and culling.

In each generation, QMSim writes the temporary data in "data.tmp". Then it executes the "external solver". The external solver should read "data.tmp" and genotypes information (if required) and calculates breeding values then it should write EBVs in "my_bv.txt". After external solver finished, QMSim reads "my_bv.txt" and use the EBVs to select or cull parents for simulation of next generation.

File "data.tmp" contains a header line, animals ID, sire ID, dam ID, FLAG,

sex, generation number, number of male and female progeny, inbreeding, homozygosity, phenotype, residual, Polygene and QTL. Flag indicates whether the animal is sire (S), dam (D) or progeny (P). File "my_bv.txt" should contain a header line, animals ID and EBV.

Population specific parameters for saving outputs:

begin_p	opoutput & end_ popoutp	out		
Description:	Beginning and end of output options for the population			
Usage:	begin_popoutput;			
	end_ popoutput;			
Type:	Mandatory			
crossove				
Description:	Save all crossovers that occurred in the recent population			
Usage:	e: crossover option;			
	option /gen v1 v2 v3	save crossovers occurred in specified generations. v1 v2 v3		

	are generation numbers for which
	crossovers should be saved.
Type:	Optional
Note:	File name = "population name"_crosso_"replicate number".txt

data

Description: Usage:	: Save individual's data except their genotypes data option;		
Usage.	▲ ·		
	option	/gen v1 v2 v3	save data for specified generations.
	1	C	v1 v2 v3 are generation numbers
			for which data should be saved.
Type:	Optional		
Note:	File name = "po	pulation name"_data_"	replicate number".txt
		1 0 0	neration number, number of male and sity, and genetic and residual values.

stat

Description:	Save brief statistics on simulated data		
Usage:	stat;		
Type:	Optional		
Note:	File name = "population name" stat "replicate number".txt		
	The stat file contains mean and standard deviation for inbreeding,		
	homozygosity, phenotypes and its components, and information on structure		

of simulated population.

allele_fr	eq		
Description:	Save allele fre	quencies	
Usage:	allele_freq option;		
-	option	/mafbin v	v is the number of bin for minor allele frequency distribution
		/gen v1 v2 v3	save allele frequencies for specified generations. v1 v2 v3 are generation numbers for which allele frequencies should be saved.
Type:	Optional		•
Note:	Marker file na	me = "population name	" freq_mrk "replicate number".txt
	QTL file name	e = "population name"	freq_qtl_"replicate number".txt
	To save memo	ory only non-zero allele	frequencies are stored.
	Minor allele fr	equency distribution is	printed at the end of the file.

genotype

Description:	Save genotype d	ata		
Usage:	genotype option;			
-	option	/binary	save genotypes in binary format (to	
			save memory)	
		/snp_code	save SNP as genotype code (i.e. 0 2	
			3 4 5; 0=homozygote for allele 1,	
			2=homozygote for allele 2,	
			3=heterozygote the first allele is	
			from sire and the second allele is	
			from dam, 4=heterozygote the first	
			allele is from dam and the second	
			allele is from sire, 5=missing)	
		/seq	save SNP and bi-allelic QTL in the	
			same file with genotype code: 0 2 3	
			4 5 (see /snp_code for genotype	
			code description)	
		/gen v1 v2 v3	save genotype for specified	
			generations. v1 v2 v3 are	
			generation numbers for which	
Tyme	Ontional		genotype should be saved.	
Type:	Optional Markar file name	- "nonulation nomo"	mrk "ranligata numbar" tyt	
Note:	Marker file name = "population name"_mrk_"replicate number".txt			
	QTL file name = "population name"_qtl_"replicate number".txt The file contains animal ID and genotypes (two alleles for each locus). The			
		es is as same as the or		
			for animal ID and 4 bytes for each	

marker (2 bytes for each allele). This format is repeated for every individual. Options binary and snp_code cannot be used together.

ld

Description: Usage:	Save linkage disequilibrium stat ld option;				
	option	/maft v	v is minor allele frequency threshold for ld calculation. Markers with minor allele frequency less than v will be excluded. Default is 0.05.		
		/max_distance v	v is the maximum distance between two markers. Marker pairs with greater distance are ignored. Default is 5 cM.		
		/nmrk v	v is the number of markers to be considered for LD calculation. Marker will be selected randomly.		
		/chr v1 v2 v3	Calculate LD statistics for specified chromosome. v1 v2 v3 are chromosome numbers. Default is the longest chromosome.		
		/gen v1 v2 v3	save ld data for specified generations. v1 v2 v3 are generation numbers for which ld data should be saved		
Type:	Optional				

Type: Note:

File name = "population name" ld "replicate number".txt

The extent of LD is an important factor in association studies. Different LD measures can give substantially different estimates of LD. Each measure might be preferable in certain situations. Therefore extend of LD is calculated based on three different measures of LD and the user should decide which one to use.

1) Pooled square of the correlation between loci A and B:

$$r^{2} = \sum_{i=1}^{m} \sum_{j=1}^{n} p(A_{i}) p(B_{j}) r_{ij}^{2}$$

where

$$r_{ij}^{2} = \frac{D_{ij}^{2}}{p(A_{i})(1 - p(A_{i}))p(B_{j})(1 - p(B_{j}))}$$

and

$$D_{ij} = p(A_i B_j) - p(A_i) p(B_j)$$

2) Lewontin's LD measure:

$$D' = \sum_{i=1}^{m} \sum_{j=1}^{n} p(A_i) p(B_j) \left| \frac{D_{ij}}{D_{ij}^{\max}} \right|$$

If $D_{ij} < 0$

$$D_{ij}^{\max} = \min(p(A_i)p(B_j), (1 - p(A_i))(1 - p(B_j)))$$

If $D_{ij} \ge 0$

$$D_{ij}^{\max} = \min(p(A_i)(1 - p(B_j)), (1 - p(A_i))p(B_j))$$

3) Standardized chi-square measure:

$$\chi^{2} = 2N \sum_{i=1}^{m} \sum_{j=1}^{n} \frac{D_{ij}^{2}}{p(A_{i})p(B_{j})} / 2N \min(m, n)$$

where 2N is the number of haplotypes.

4- GENOME SECTION:

begin_genome & end_genome

Description:	Beginning and end of the genome section
Usage:	begin_genome;
	end_genome;
Type:	Mandatory

Defining chromosomes:

begin_chr & end_chr

Description:	Beginning and er	nd of chromosome parameters	
Usage:	begin_chr = value;		
	value	is the number of chromosomes with the same parameters	
		Range: $1 - 500$	
	end_chr;		
Type:	Mandatory		
Note:		with different parameters should be defined separately. In asomes can be simulated.	

chrlen

Description:	Chromosome len	lgth
Usage:	chrlen = value;	
	value	is the chromosome length

Range: 1	-10,000	cМ
----------	---------	----

Type: Mandatory

nmloci

Description:	Number of marker loci on the chromosome		
Usage:	nmloci = value;		
	value	is the nu	mber of marker loci
		Range:	0-400,000
Type:	Mandatory		

mpos

Description:	Marker positions		
Usage1:	mpos = even option;		
-	even	evenly spaced	
Usage2:	mpos = rnd optio	n;	
	rnd	random; samples from uniform distribution in each	
		replicate	
Usage3:	mpos = rnd1 option;		
	rnd1	random; samples from uniform distribution in the first	
		replicate only (fixed across replicates)	
	option	/start v v is start position	
		/end v v is end position	
Usage4:	mpos = pd v1 v2	v3;	
	pd	predefined	
	v1 v2 v3	are marker positions	
Type:	Mandatory	-	

nma

Description: Usage1:	Number of marker alleles in the first historical generation $nma = all v;$	
8	all	all loci would have same number of alleles initially
	V	number of alleles
Usage2:	nma = rnd v1 v2	v3;
C	rnd	random; samples from uniform distribution in each
		replicate
	v1 v2 v3	number of marker alleles
Usage3:	nma = rnd1 v1 v2	2 v3;
	rnd1	random; samples from uniform distribution in the first
		replicate only (fixed across replicates)
	v1 v2 v3	number of marker alleles
Usage4:	nma = pd v1 v2 v	/3;
	1	predefined
	v1 v2 v3	number of marker alleles

		Range: $1 - 255$ for 8-bit version and $1 - 65535$ for 16-bit
		version
Usage5:	nma = unique;	number of alleles is 2 times of the number of individuals
-	_	in the first historical generation
Type:	Mandatory	
Note:	In the subseque	nt historical generations, the number of alleles per locus
	might increase by	y mutation.

maf

mai				
Description:	Marker allele frequencies in the first historical generation			
Usage1:	maf = eql;			
	eql	equal		
Usage2:	maf = rnd;			
-	rnd	random; samples from uniform distribution in each replicate		
Usage3:	maf = rnd1;	1		
C	rnd1	random; samples from uniform distribution in the first replicate only (fixed across replicates)		
Usage4:	maf = all v1 v2 v			
O suger.	all	all loci would have the same allele frequencies (The		
	all	number of alleles for all loci should be the same)		
	v1 v2 v3	are marker allele frequencies (The allele frequencies must		
	VI V2 VJ	sum to one). The number of input values is the number of		
		alleles.		
		Range: $0-1$		
Usage5:	$maf = pd v1 v2 v3 \dots;$			
Obuges.	pd	predefined		
	v1 v2 v3	are marker allele frequencies (The allele frequencies must		
	vi v2 v5	sum to one within each marker). The total number of input		
		values should be sum of the number of alleles for all loci.		
		Range: $0-1$		
Type:	Mandatory			
Note:	Allele frequencies will be simulated in the first historical generation. In the			
	-	erations, allele frequencies might be changed by drift and		
nqloci				
Description:	Number of QTL loci on the chromosome			
T .				

Description:	Number of QTL	loci on th	e chromosome
Usage:	nqloci = value;		
	value	is the nu	umber of QTL loci
		Range:	0 - 50,000
Type:	Mandatory		

qpos

11					
Description:	QTL positions				
Usage1:	qpos = even optio	on;			
	even	evenly			
Usage2:	qpos = rnd option	l;			
	rnd	random; samples from uniform distribution in each			
		replicate			
Usage3:	qpos = rnd1 option;				
	rnd1	random; samples from uniform distribution in the first replicate only (fixed across replicates)			
	option	/start v v is start position			
		/end v v is end position			
Usage4:	$qpos = pd v1 v2 v3 \dots;$				
-	pd	predefined			
	v1 v2 v3	are QTL positions			
Type:	Mandatory	-			

nqa

Description:	-	alleles in the first historical generation
Usage1:	nqa = all v;	
	all	all loci would have same number of alleles initially
	V	number of alleles
Usage2:	nqa = rnd v1 v2 v	v3;
	rnd	random; samples from uniform distribution in each
		replicate
	v1 v2 v3	number of QTL alleles
Usage3:	nqa = rnd1 v1 v2	v3;
	rnd1	random; samples from uniform distribution in the first
		replicate only (fixed across replicates)
	v1 v2 v3	number of QTL alleles
Usage4:	nqa = pd v1 v2 v	3;
	pd	predefined
	v1 v2 v3	number of QTL alleles
		Range: $1 - 255$ for 8-bit version and $1 - 65535$ for 16-bit
		version
Type:	Mandatory	
Note:	In the subsequen	t generations, the number of alleles per locus might increase
	by mutation.	
	-	

qaf

Description:	QTL allele freque	ency in the first historical generation
Usage1:	qaf = eql;	
	eql	equal

Usage2:	qaf = rnd; rnd	random; samples from uniform distribution in each replicate
Usage3:	qaf = rnd1; rnd1	random; samples from uniform distribution in the first replicate only (fixed across replicates)
Usage4:	qaf = all v1 v2 v3 all v1 v2 v3	
Usage4:	qaf = pd v1 v2 v3 pd v1 v2 v3	0
Type: Note:	-	es will be simulated in the first historical generation. In the rations, allele frequencies might be changed by drift and

qae

yac		
Description:	QTL allele effect	
Usage1:	qae = pd v1 v2 v3	3;
	pd	predefined
	v1 v2 v3	are percentage of QTL variances (should sum up to one)
	Note:	QTL allelic effects will be sampled from gamma distribution with shape 0.4
Usage2:	qae = rndg v;	-
-	rndg	Effects are sampled from gamma distribution
	V	gamma shape
Usage3:	qae = rndn;	
	rndn	Effects are sampled from normal distribution
Usage4:	qae = rnd;	
	rnd	Effects are sampled from uniform distribution
Type:	Mandatory	
Note:	QTL allelic effect	ts are simulated in the last historical generation.
	QTL allelic effect	ets are first sample based on the specified distribution (i.e.,
	gamma, normal	or uniform distribution) and then are scaled such that the
	sum of QTL vari	ances in the last historical generation equals the input QTL
	variance.	

Scaling is done as follows:

- 1) QTL value at each locus is calculated as sum of alleles 1 and 2
- 2) For each QTL, mean in the last HP is computed
- 3) For each animal in the last HP, sum of QTL values is calculated. This is true genetic value due to QTLs. Then observed variance is obtained for the last HP.
- 4) Scale = sqrt(Input QTL variance) / sqrt(Observed QTL variance)
- 5) Then QTL allelic effects at each locus are scaled as (allelic effect QTL mean) \times Scale

When relative QTL variances are specified as input values (predefined), allelic effects of each QTL are scaled separately to ensure the right variance for each QTL.

male_map_scale

Description:	Scale factor to shrink or expand linkage map for males	
Usage:	male_map_scale = value;	
	value is the scale factor	
	Range: $0-5$	
Type:	Optional	
Default:	1	
Note:	Crossover will be modeled based on the scaled map.	
	If interference has been specified, interference will also be scaled and	
	therefore interference might become different between sexes.	
	If male_map_scale is specified, new map for males will be printed in linkage	
	map output file.	

female_map_scale

Description:	Scale factor to shrink or expand linkage map for females		
Usage:	female_map_scale = value;		
	value is the scale factor		
	Range: $0-5$		
Type:	Optional		
Default:	1		
Note:	Crossover will be modeled based on the scaled map.		
	If interference has been specified, interference will also be scaled and		
	therefore interference might become different between sexes.		
	If female_map_scale is specified, new map for females will be printed in		
	linkage map output file.		

cld

Description:	Generate comple	te linkage disequilibrium in the first historical generation
Usage1:	cld = m;	generate complete LD between markers
Usage2:	cld = q;	generate complete LD between QTL

Usage3:	cld = m q;	generate complete LD between markers and between QTL, separately (i.e., no LD between markers and QTL)
Usage4:	cld = mq;	generate complete LD between markers, between QTL and between markers and QTL. In this case markers and QTL should have the same number of alleles.
Type:	Optional	
Note:	should be met: 1 n' for markers or loci (i.e., 'eql' or When complete	LD between QTL is considered, there should be few tions to create variation between individuals before starting

select_seg_loci

Description:	Select segregating loci in the last	historical generation. Only selected loci are
	used to simulate recent population	h(s)
Usage:	select_seg_loci option;	
	option /maft v	v is minor allele frequency threshold. Loci with minor allele frequency larger than or equal to v will be selected
	/nmrk v	v is the number of markers to be selected randomly
	/nqtl v	v is the number of qtl to be selected randomly
Type:	Optional	-
Default:	None	
Note:	When one simulate a large number of historical generations to approach mutation-drift equilibrium, a large proportion of loci are fixed in the last historical generation. Because QMSim does not simulate mutation in recent populations, non-segregating loci are not useful. Therefore, getting rid of the non-segregating loci in the last historical generation can save substantial amount of time and memory.	
	historical generation will be selec	s command all segregating loci in the last eted. If 'maft' is specified selection will be y and then based on the number of markers
	-	ters or QTL is smaller than that specified, a d.

Description:	Randomize marker positions across genome in each replicate
Usage:	r_mpos_g;
Type:	Optional
Default:	None

r1_mpos_g

Description:	Randomize marker positions across genome in the first replicate only (fixed
	across replicates)
Usage:	r1_mpos_g;
Type:	Optional
Default:	None

r_qpos_g

Description:	Randomize QTL positions across genome in each replicate
Usage:	r_qpos_g;
Type:	Optional
Default:	None
Type:	Optional

r1_qpos_g Description: Randomize QTL positions across genome in the first replicate only (fixed across replicates) Usage: r1_qpos_g; Optional Type: Default: None

rmmg

Description:	Rate of missing marker genotypes		
Usage:	rmmg = value op	otion;	
	value	is the rate of missing marker genotypes	
		Range: $0 - 0.5$	
	option	/rndg v	Missing rates are sampled from gamma distribution with shape v
Type:	Optional		
Default:	0		
Note:	Vote: If one is interested in having the true genotypes as well, the scenario should be re-run with the same seed with rmmg, rmqg, rmge and rqge commented		enotypes as well, the scenario should
			ng, rmqg, rmge and rqge commented
	out.		
	Missing genotyp	es are simulated in the	e last step when writing the genotypes
	-		e of alleles from one generation to
	another is not genotypes.	interrupted and all r	eported statistics are based on full

rmqg

Description:	Rate of missing QTL genotypes
Usage:	The same as for rmmg

rmge

Description:	Rate of marker genotyping error		
Usage:	rmge = value option;		
	value	is the rate of mark	er genotyping error
		Range: $0 - 0.2$	
	option	/rndg v	Error rates are sampled from gamma distribution with shape v
Type:	Optional		
Default:	0		
Note:			

rqge

Description:	Rate of QTL genotyping error
Usage:	The same as for rmge

mmutr

Description:	Marker mutation rate in historical population		
Usage:	mmutr = value option;		
	value	is mutation arte	
		Range: $0 - 0.01$	
	option	/recurrent	recurrent mutation
Type:	Optional		
Default:	0		
Note:	By default, the	mutation model is in	finite-allele model.
	In recurrent mutation process, no new allele is generated instead the allel state is altered from one to another. However, with recurrent mutation		
	model, if the r	number of alleles for	a locus is one the locus will be treated
	as bi-allelic locus. This allows one to simulate SNP when the first		
	historical gene	eration is fixed for a	ll loci (i.e., non-segregating).

For SNP recurrent mutations are generally very rare and there is no evidence to indicate that mutation contributes significantly to the erosion of LD between SNP (Ardlie et al., 2002).

The number of mutations per individual is sampled from a Poisson distribution with mean u (u = 2 * number of loci * mutation rate) and then each mutation is assigned to a random locus in the genome.

It is important to note that in recent populations no mutation is generated. This is because usually recent populations involve small number of generations for which the effect of mutation might be neglected.

qmutr

Description:	QTL mutation rate in historical population		
Usage:	qmutr = value option;		
	value	is mutation arte	
		Range: $0 - 0.01$	
	option	/recurrent	recurrent mutation
Type:	Optional		
Default:	0		
Note:	See mmutr		

interference

Description:	Interference		
Usage:	interference = value option;		
	value	is interference based on distance in cM	
		Range: 0.01 – 500.0	
	option	/c complete interference	
Type:	Optional		
Default:	no interference		
Note:	1		
	- Locations	s of crossovers along chromosomes are assigned at random ce between pair of crossovers (<i>dis</i>) is smaller than the	

If interference is complete or if URND < $(1 - \frac{dis}{value})^2$: delete one of the two crossovers at random

URND is a uniform random deviate. No chromatid interference is assumed.

mean_crossover

Description:	Mean crossover per 1 Morgan	
Usage:	mean_crossover = value;	
	value	is the mean crossover per 1 Morgan Range: $0-5$
Type:	Optional	C
Default:	1	

5- OUTPUT SECTION:

begin_output & end_output

Description: Beginning and end of the output section Usage: begin_output; end_output; Type: Mandatory

output_folder

Description:	Output folder	
Usage:	output_folder = st	ring;
	string	path to the folder where output files will be written
Type:	Optional	
Default:	Default output fol	der name is r_"parameter file name"

attach_rep

Description:Append output files over replicatesUsage:attach_rep;Type:Optional

linkage_map

Description:	Save linkage map
Usage:	linkage_map;
Type:	Optional

Note: Marker linkage map file name = lm_mrk_"replicate number".txt QTL linkage map file name = lm_qtl_"replicate number".txt

allele_effect

Description:	Save allele effects
Usage:	allele_effect;
Type:	Optional
Note:	File name = effect_qtl_"replicate number".txt

allele_label

Description:	Save starting allele labels
Usage:	allele_label;
Type:	Optional
Note:	If this command is not specified, allele labels are converted to consecutive numbers starting from 1 at last historical generation. This recoding reduces the genotype file size. If one needs to trace alleles from founders (when starting alleles are unique) then allele_label should be specified.

hp_stat

Description:	Save brief statistics on historical population		
Usage:	hp_stat;		
Type:	Optional		
Note:	File name = hp_stat_"replicate number".txt		
	The output mainly contains statistics on the genome in the last historical		
	generations		

monitor_hp_homo

Description: Usage:	Save the mean marker and QTL homozygosity of the historical population monitor_hp_homo option;			
Usage.				
	option	/freq value		
		value	is the output frequency. For	
			example, if value is 100, the mean	
			homozygosity will be reported	
			every 100 generations.	
			Range: $1 - 10,000$	
			Default: 50	
Type:	Optional			
Note:	Marker file name = hp_homo_mrk_"replicate number".txt			
	QTL file name = hp_homo_qtl_"replicate number".txt			
	Monitoring homozygosity in HP generations helps to find optimum number			
	of generations required to reach mutation-drift equilibrium. Once the			
	-	-	nmand can be disabled to speed up the	

Running the application

QMSim [parameter filename] -o

If *parameter file name* is not specified, program will prompt the user to enter it. Option *-o* forces the program to overwrite output folder if already exists.

Examples

Example 1: Simulating 10k SNP panel in population of 10 discrete generations and with no historical generations. All loci are in linkage equilibrium in the founders.

```
** Global parameters **
 title = "Example 1 - 10k SNP panel";
nrep = 1;
                          //Number of replicates
//Heritability
h2 = 0.2;
qtlh2 = 0.2;
                               //QTL heritability
phvar = 1.0;
                                //Phenotypic variance
/********

Example 8: Simulating a pure polygenic trait (no markers and no QTLs are simulated). As QMSim simulates a genome, the genome section in the parameter file is mandatory. However, for simulating a pure polygenic trait, user should do the following:

1- Set qtlh2 to zero

- 2- No historical generations are needed, so set nhg to zero
- 3- Define one chromosome
- 4- Set the number of markers and QTL to zero

5- Set other genome parameters to valid arbitrary values

```

Note that parameters for all examples given above have been chosen arbitrarily and may not represent a realistic situation. Examples are only provided to help users to get a quick start with QMSim.

Example of simulation diagram:

Decay of linkage disequilibrium in a simulated data set using QMSim:

When an infinite population undergoes random mating and random selection, the amount of linkage disequilibrium between two adjacent loci is expected to decay exponentially over generations at rate equal to recombination rate. We have investigated the decay of LD in a simulated population obtained by QMSim. The population consisted of 500 sires and 500 dams in each generation which were mated and selected at random for 100 discrete generations. Different marker densities were considered. In the first generation, markers were forced to be in complete LD with each other (see next page for the parameter file). The following graph (Figure 1) shows the decay of LD between adjacent markers for different recombination rates observed in the simulated data set.

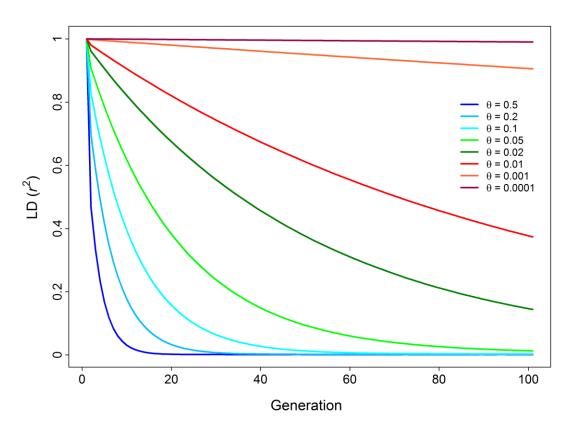

Figure 1. Observed decay of linkage disequilibrium (LD) between adjacent marker pairs for different recombination rates (θ) in a simulated data set using QMSim.

Parameter file for assessing decay of LD using QMSim

Observed inbreeding vs. expected inbreeding:

Inbreeding is an important parameter in the population and evolutionary genetics. The mean population inbreeding coefficient at generation t can be predicted as $F_t = 1 - (1 - \frac{1}{2Ne})^t$, where Ne is the initial effective population size. To investigate whether QMSim generates inbreeding properly, observed average inbreeding coefficients for different effective population sizes (20, 50, 100, 200 and 500) against generations were plotted. The observed average inbreeding coefficients were well in agreement with the expected ones. Results are shown in Figure 2. For details of the simulated population structure, see parameter file in below.

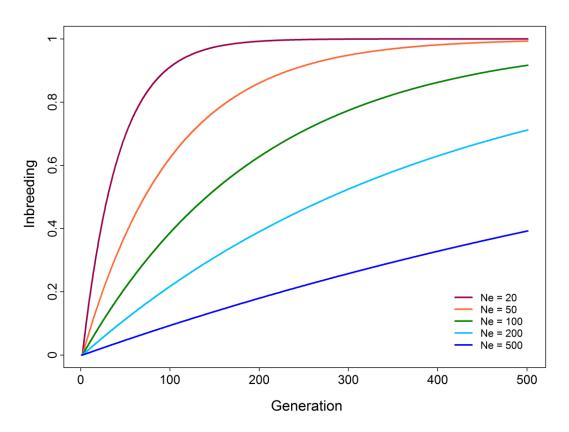

Figure 2. Observed average inbreeding coefficients over generations for different effective population sizes (*Ne*).

Parameter file for assessing inbreeding:

Mutation-drift equilibrium:

Genetic variability is generated by mutation but it is lost randomly over generations through genetic drift. The amount of new variation depends on the mutation rate and loss of variation due to fixation of alleles depends on effective population size.

Let's assume that alleles are neutral (no selection) and that offspring s in each generation are produced from random union of gametes from N males and M females. Over generations, mutation and genetic drift act in opposite directions. However after certain number of generations the population reaches mutation-drift equilibrium where the population maintains a certain amount of variation. At equilibrium $F_t = F_{t-1} = F_{t-2} = F$. Under infinite-allele mutation model F is approximately $\frac{1}{1+4Neu}$ and proportion of heterozygous loci is 1-F or $H \approx \frac{4Neu}{1+4Neu}$ (Crow and Kimura, 1970), where u is the mutation rate. Under infinite-allele model, mutation creates new unique allele that never existed in the population.

For finite-allele model, mutation does not create novel allele but rather modifies an allele to another allele within the allelic space with the same probability. Recurrent mutation can be reversible. At equilibrium F is approximately $\frac{1+\frac{4Neu}{k-1}}{1+\frac{4Neuk}{k-1}}$, where k is the number of possible alleles.

In the following we assessed the distribution of allele frequencies at mutation-drift equilibrium for neutral alleles under assumption of random union of gametes from N males and M females. Here we have simulated bi-allelic markers mimicking SNP markers, which follow a recurrent mutation model. When 4Neu is smaller than 1, close to 1 or larger than 1, at mutation-drift equilibrium a U-shape, uniform or normal distribution of allele frequencies is expected, respectively (Wright, 1931). Six different scenarios were considered. Parameters for these scenarios are shown in Table 1.

Parameters	Scenario 1	Scenario 2	Scenario 3	Scenario 4	Scenario 5	Scenario 6
Ne	100	1,000	1,000	500	1,000	2,000
и	2.5e-4	2.5e-5	2.5e-5	2.5e-4	2.5e-4	2.5e-4
4Neu	0.1	0.1	0.1	0.5	1	2
No. of SNP	10,000	10,000	10,000	10,000	10,000	10,000
Initial allele freq.	fixed	fixed	0.5	fixed	fixed	fixed
	1,000	1,000	1,000	1,000	1,000	1,000
	5,000	5,000	2,000	5,000	5,000	5,000
	10,000	10,000	5,000	10,000	10,000	10,000
	20,000	20,000	10,000	20,000	20,000	20,000
		40,000				
		60,000				
No. of replicates	100	100	100	100	100	100

Table 1. Parameters for different scenarios of mutation-drift equilibrium.

For all scenarios equal numbers of males and females were considered, matings were based on random union of gametes and mutation and counter-mutation rates are assumed to be equal. Results for each scenario are shown in Figures 3 to 7.

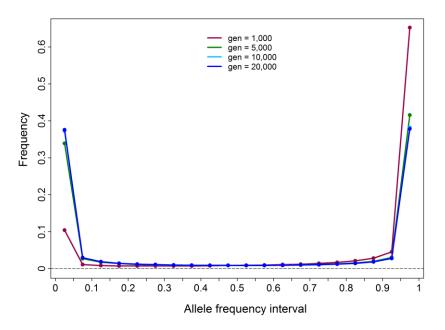

Figure 3. Distribution of allele frequencies for scenario 1.

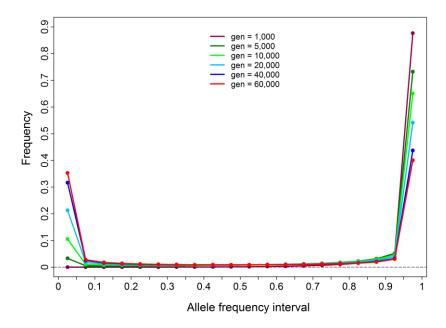

Figure 4. Distribution of allele frequencies for scenario 2.

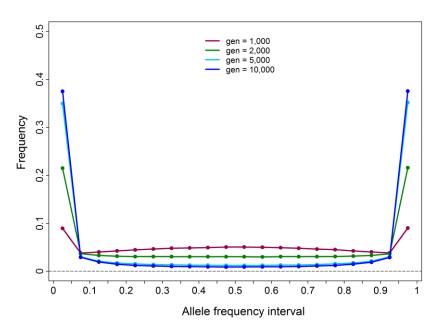

Figure 5. Distribution of allele frequencies for scenario 3.

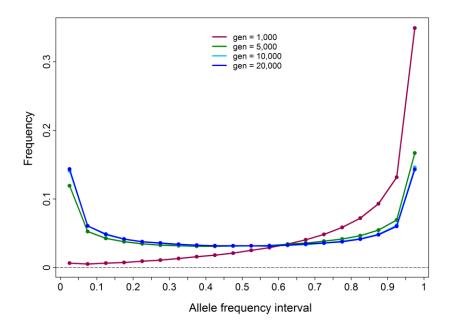

Figure 6. Distribution of allele frequencies for scenario 4.

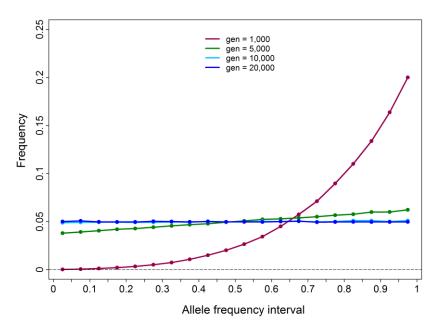

Figure 7. Distribution of allele frequencies for scenario 5.

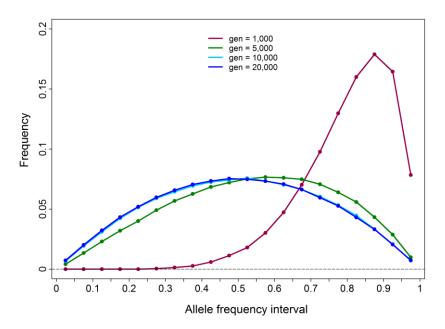

Figure 8. Distribution of allele frequencies for scenario 6.

From graphs 3 and 4 (scenarios 1 and 2) it can be seen that when 4*Neu* is constant but *Ne* differs, allele frequencies approach mutation-drift equilibrium slower with larger *Ne*.

Comparing graph 4 to graph 5 (scenario 2 to scenario 3) shows that when allele frequencies are equal (0.5) in the first generation instead of fixed (1.0), they approach their steady-state frequencies much quicker. Graphs 6, 7 and 8 show the distribution of allele frequencies for different values of 4Neu.
